## ABSTRACT

During 14 through 20 June 1991, an active acoustics exercise was conducted under the auspices of the Program Executive Officer of the Air, ASW, Assault and Special Mission Programs office. This exercise was located on the continental shelf, slope and in the basin between the Florida Keys and St. Petersburg, Florida . The objective of this mission is to make noise, reverberation and transmission loss measurements using fully calibrated sources, receivers, and recording devices. This data set is intended to support the validation of candidate shallow-water transmission loss and reverberation models for use in the development of next generation airborne ASW sensor systems. To adequately interpret the exercise results and to support the modeling effort, a robust suite of supporting environmental measurements were made aboard the research vessel NADC-38, owned by the Naval Air Development Center (NADC). These measurements include a depiction of the sound speed structure, bathymetry, meteorological conditions, and navigation along 11 projector tow tracks and at 3 drifting ambient noise and 4 reverberation sites. This technical note provides a brief description of the oceanographic and geological structure in the exercise area followed by a compendium of the collected data.

#### **ACKNOWLEDGMENTS**

The tasking support provided by Mr. Earle Benson (Program Executive Officer) of the Air, ASW, Assault and Special Mission Programs office (program element 0603254N), is greatly appreciated. The authors thank Mr. J.T. Gottwald for his technical guidance during all phases of this exercise, and the officers and crew aboard the research vessel NADC-38 for their efforts which greatly enhanced the success of this mission. Mr. Joe Soileau was instrumental in the iterative process of rectifying the NADC-38 navigation.

The mention of commercial products or the use of company names does not in any way imply endorsement by the U.S. Navy or NOARL.

## **I. INTRODUCTION**

One of the tasks of the Program Executive Officer of the Air, ASW, Assault and Special Mission Programs office is to provide the ability to extend all airborne ASW sensor systems into strategic shallow-water areas to demonstrate its capability in a Limited Intensity Conflict (LIC) scenario. A prerequisite for attaining this capability is to provide for the development and assessment of active environmental acoustic sensor prediction models that are suitable for a shallow-water environment. A primary limiting factor in sensor performance prediction in such an environment is the inability to adequately predict reverberation levels. Two candidate reverberation models are currently being produced; one by the Naval Oceanographic and Atmospheric Research Laboratory (NOARL) and another by the Naval Ocean Systems Center (NOSC).

In order to evaluate these and other candidate models, a carefully controlled field exercise was conducted in the shallow-water continental shelf area between St. Thomas, U.S.V.I. and the Puerto Rico Trench during 16 through 18 May 1991. This exercise, conducted between Key West and St. Petersburg, Florida, is the second in this series. A primary goal of these exercises was to acquire measured acoustic data using fully calibrated sources, receivers, and recording devices. Specific technical objectives of this effort included the quantification of the transmission loss as a function of range and frequency and the reverberation and ambient noise levels as a function of time and frequency.

In order to provide an unambiguous interpretation of the acoustic measurements, a detailed, robust suite of supporting environmental measurements were made aboard the Naval Air Development Center's (NADC) ship NADC-38. These measurements include a depiction of the sound speed structure, bathymetry, meteorological conditions, and navigation along 11 projector tow tracks and at 3 drifting ambient noise and 4 reverberation sites. In addition, precise navigational data was collected, rectified, and source-to-receiver geometries were derived. This technical note provides a brief description of the oceanographic and geological structure in the exercise area followed by a compendium of the collected data.

## **II. EXERCISE SITE DESCRIPTIONS**

### **IIA. GENERAL**

The exercise geometry was centered around four sites on the Southwest Florida shelf, slope, and adjacent basin (figure 1). Figures 2 through 5 illustrate a plot of the navigationally rectified locations of the source towpaths at each exercise site and the approximate location of each of the drifting ambient noise measurements. At all sites the reverberation measurements were conducted within 100 yd of the nominal locations of the deployed receivers. Table 1 provides an outline of the time sequence of each exercise event. The receiver positions (one horizontal and one vertical array) for Site 1 through 3 are listed

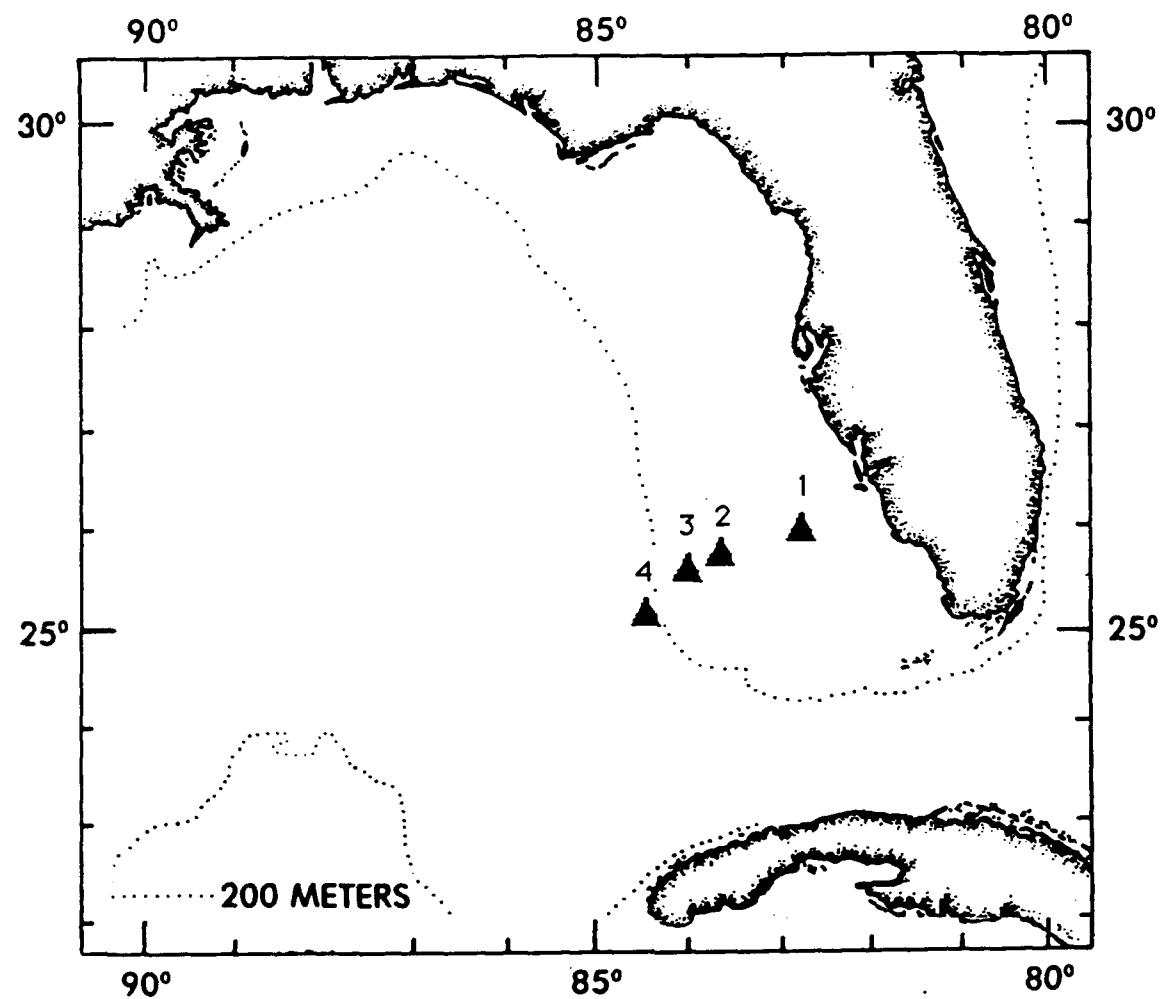

Figure 1. Location of Acoustic Data Collection Sites.

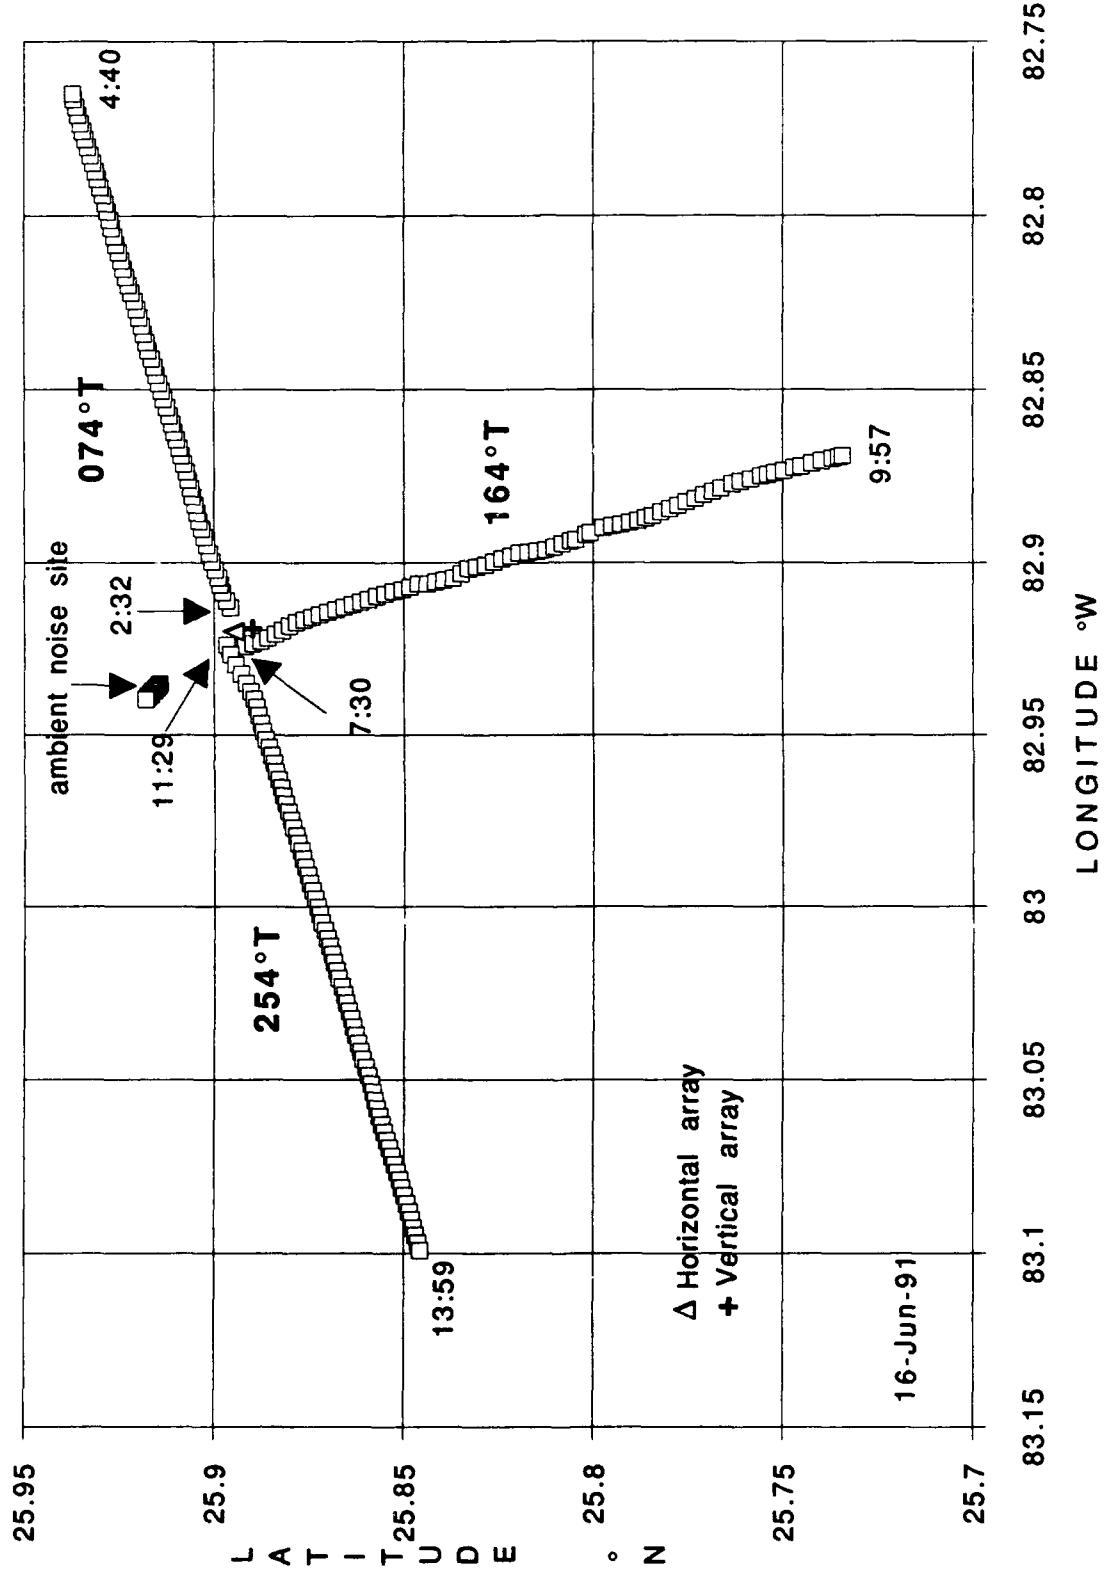

Figure 2. Acoustic Towpath Geometries and Ambient Noise Sites at Site 1.

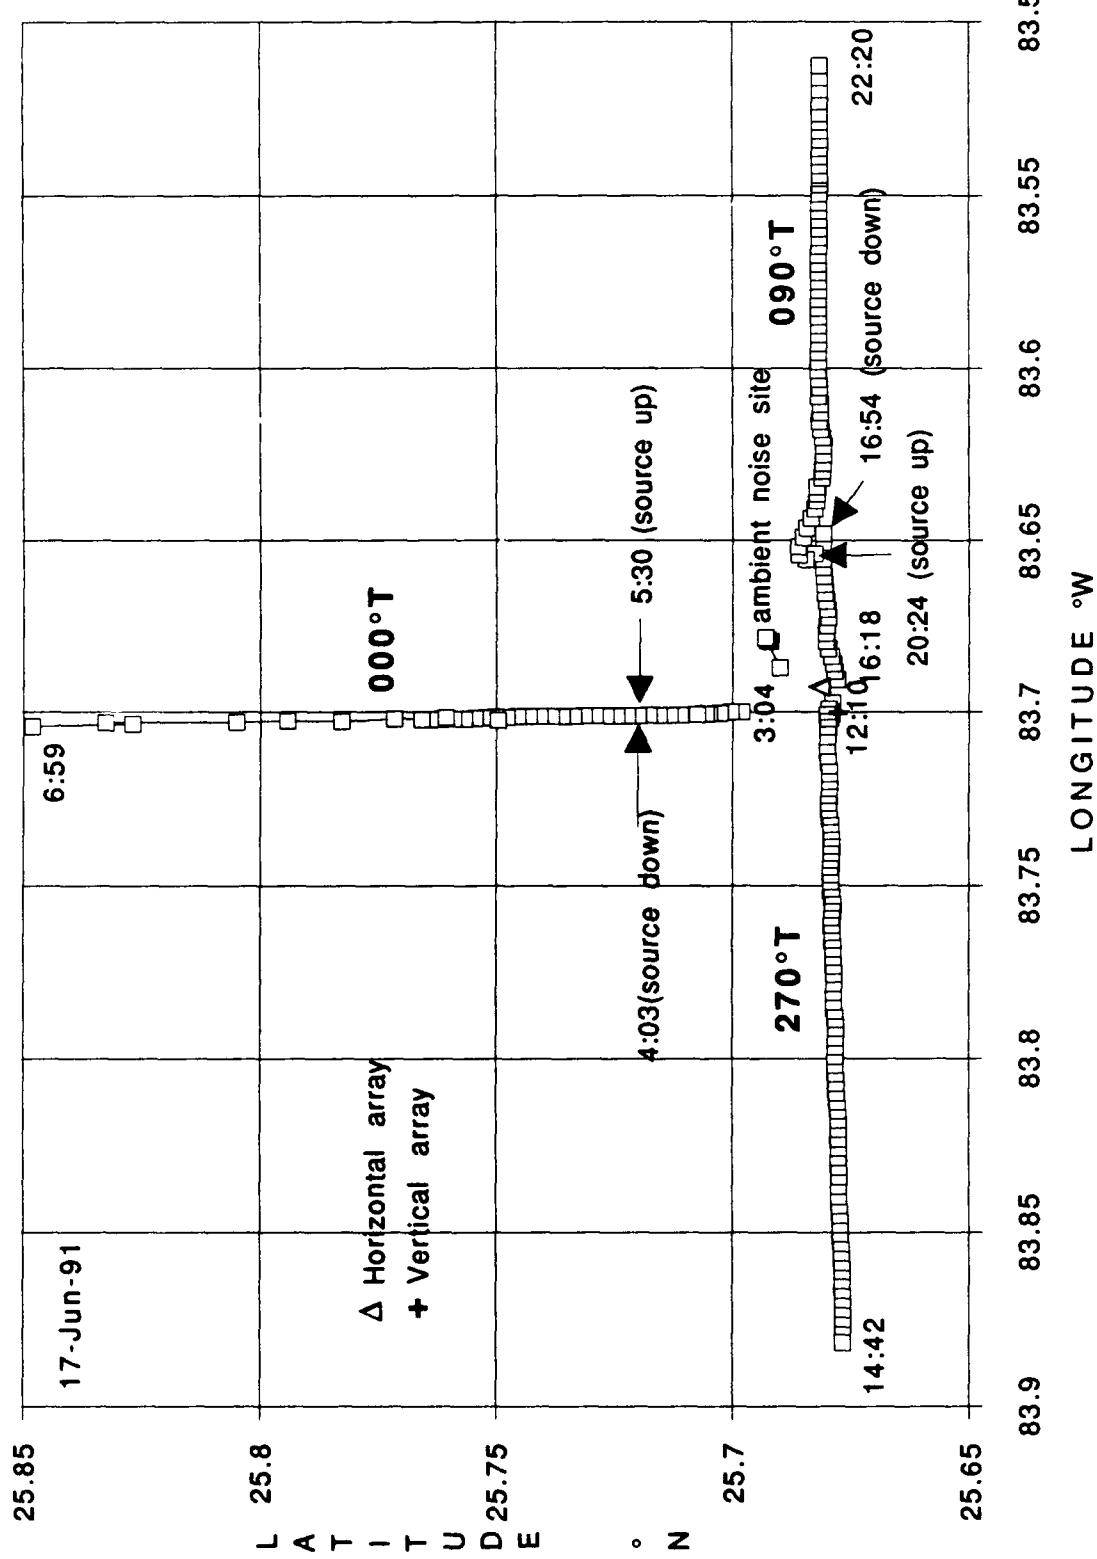

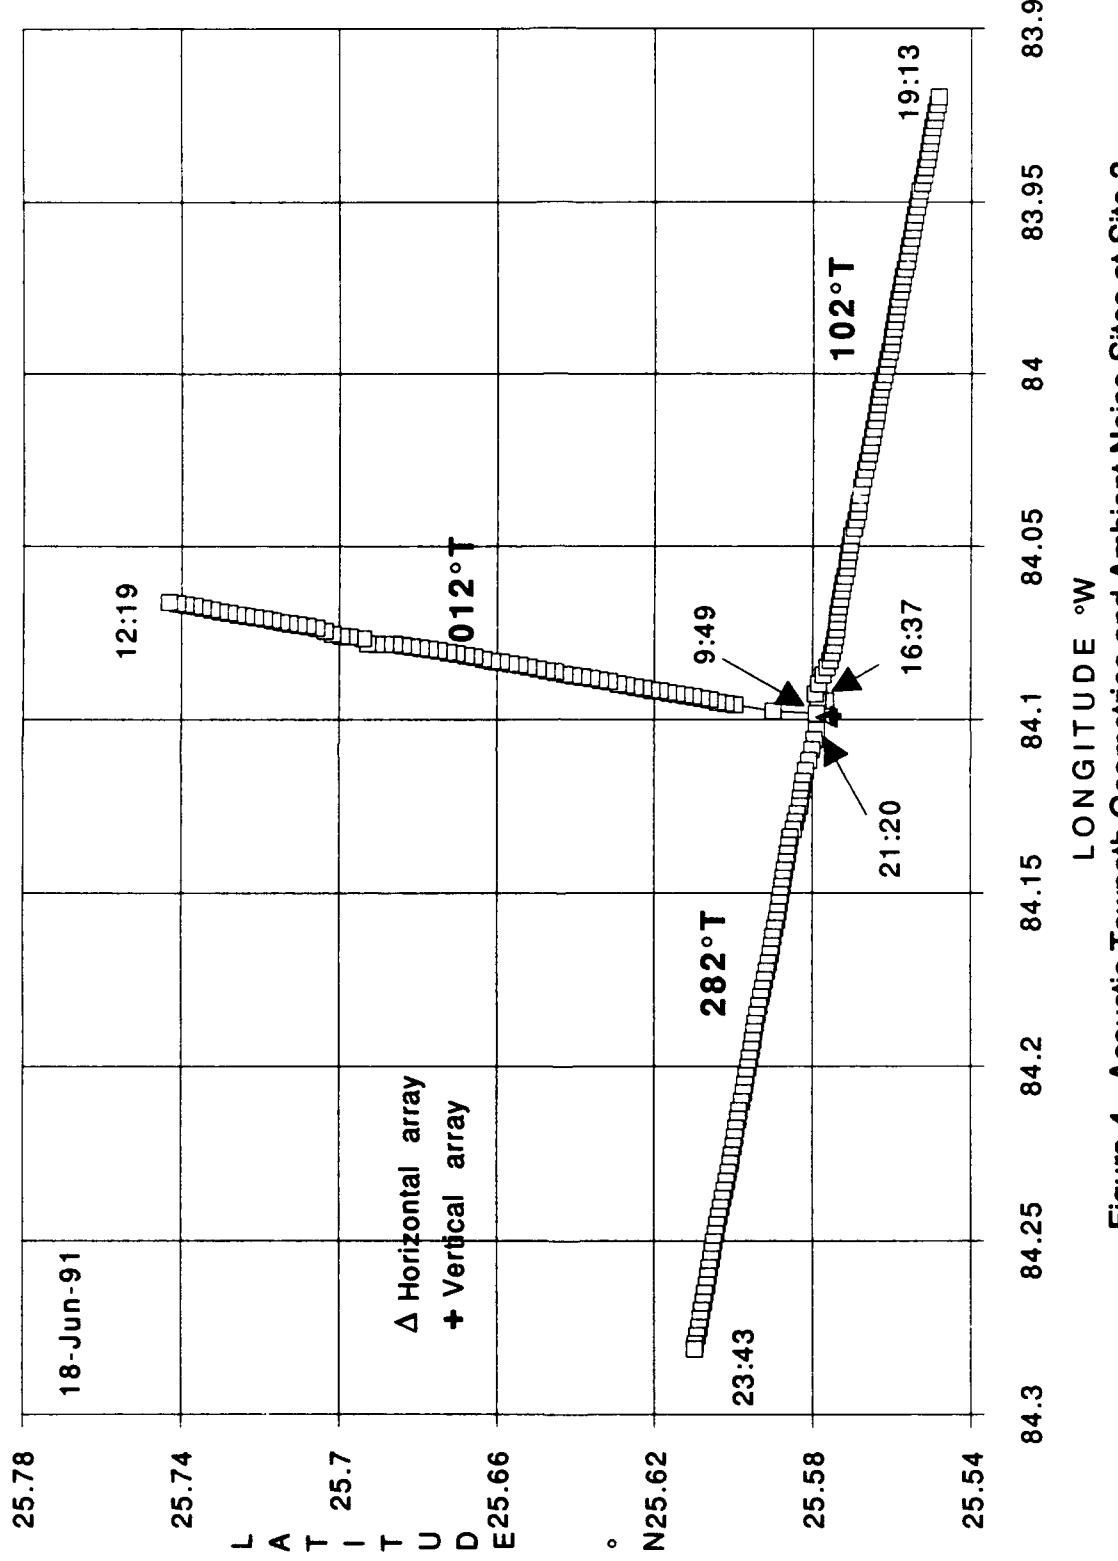

Figure 3. Acoustic Towpath Geometries and Ambient Noise Sites at Site 2.

**Figure 4. Acoustic Towpath Geometries and Ambient Noise Sites at Site 3.**

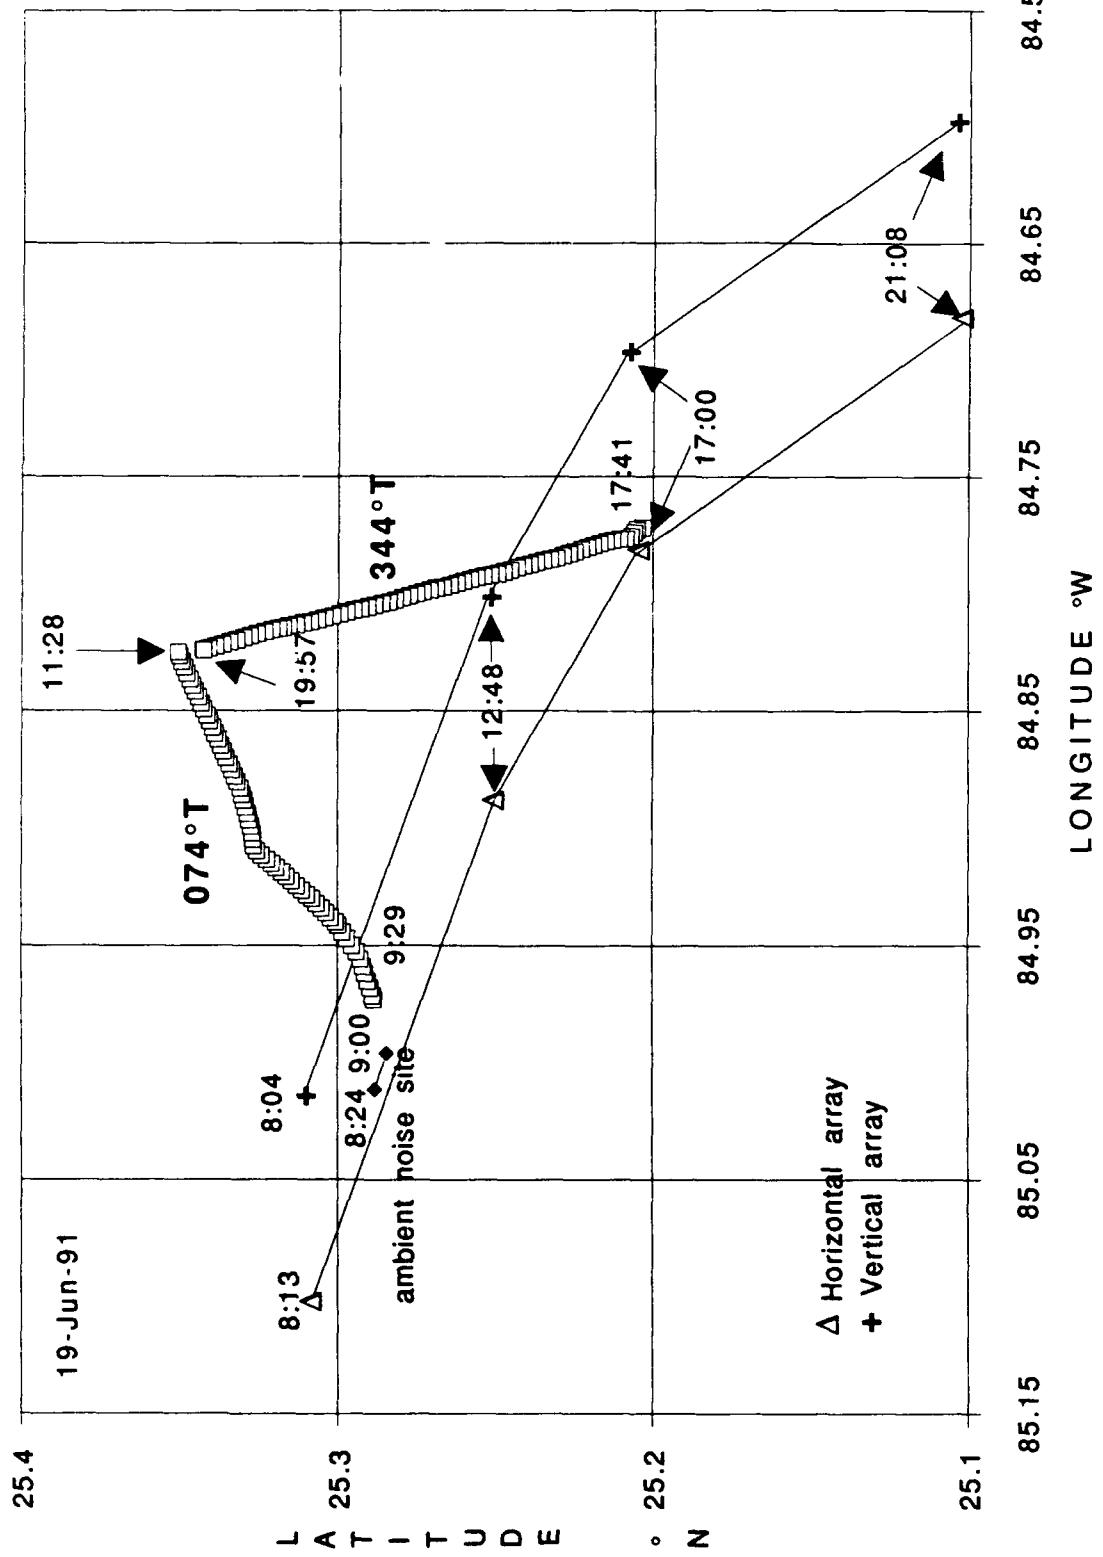

Figure 5. Acoustic Towpath Geometries and Ambient Noise Sites at Site 4.

in table 2 and were considered to be spatially stationary. Since Site 4 is located off the continental shelf and is influenced by the southeasterly flowing loop current, its position was spatially variable during the acoustic measurements. Estimated receiver positions are tabulated in appendix B.

Table 1. Time Sequence of Events

TIME (Local)	EVENT
6/15/1520-1550	Ambient noise Site 1
6/16/0100-0216	Reverberation Site 1

Table 2. Array positions during the Southwest Florida acoustic exercise.

SITE	ARRAY	LATITUDE	LONGITUDE
1	Horizontal	25°53.446'N	82°55.255'W
1	Vertical	25°53.667'N	82°55.301'W
2	Horizontal	25°40.873'N	83°41.602'W
2	Vertical	25°40.762'N	83°42.109'W
3	Horizontal	25°34.584'N	84°06.009'W
3	Vertical	25°34.795'N	84°06.104'W

Details concerning the array configuration, acoustic source emissions, and specific information pertinent to acoustic data collection will be the subject of later documentation.

## II.B. OCEANOGRAPHIC SETTING/MEASUREMENTS

The oceanography of the Southwest Florida area can be divided into three geographic regimes: the nearshore environment, the area along the continental slope and outer shelf, and the basinal environment.

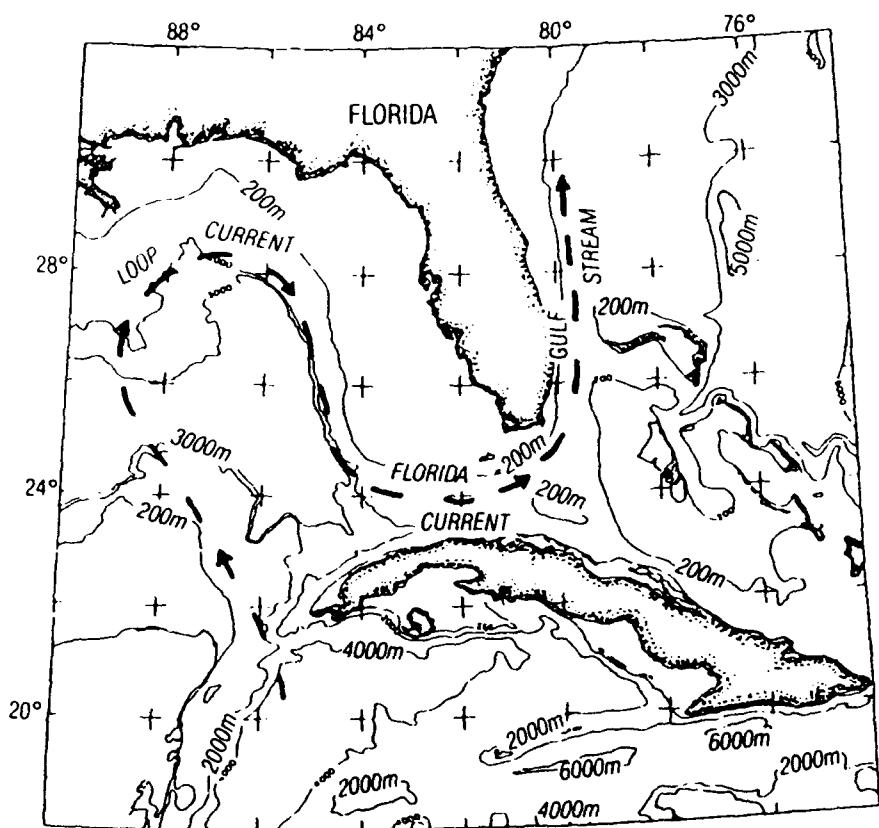

A paucity of oceanographic measurements precludes a detailed depiction of the physical processes which may precipitate significant acoustic variability, in the first two regimes. Generally, however, the nearshore environmental summer thermal structure (especially characteristic of Site 1) is highly stratified below a shallow wind-mixed layer. Since only small amounts of river runoff are

present in this area, no large variability is expected in either the temperature or salinity signatures. Generally in shelf environments, wind stress mechanisms assume a major role in causing oceanographic variability. Hence, very low winds and accompanying zero sea states were probably a major contributor to the benign conditions observed over the duration of the exercise. Tides on the shelf have a mean range of C.3 m with maximum currents of 10 cm/second (Koblinsky and Niiler, 1980). The resulting advection of about 1 km indicates that tidal net transport is important only within a few kilometers of the coastline.

The oceanographic variability along the outer continental shelf and the slope is potentially considerably greater (NECE, Inc., 1982). In this area, which includes Site 2 and especially Site 3, the interaction of the shelf water and the Loop Current creates complex eddies and frontal systems. The most prominent of these eddies are those of the Loop Current intrusions onto the shelf. Satellite imagery indicates that the interface of these dissimilar water masses at the surface is often characterized by a series of alternating cold shelf and warm Loop Current intrusions exhibiting a southwest orientation relative to the seafloor topography of the slope. Loop Current intrusions generally have length and time scales of 200 km and 15 days, respectively. In addition, there are indications that barotropic waves propagate onto the shelf to as shallow as the 40-m isobath (Kroll and Niiler, 1976). Conjectures have been made that a series of Loop Current derived northward propagating cyclonic and anticyclonic eddy fields along the 150-m isobath are present in this area. The present historical sound speed databases do not allow the quantification of these proposed outer shelf/slope mechanisms. During the exercise, the environment at Site 3 was benign. No Loop Current or any other dynamic processes were present to precipitate meaningful acoustic variability in the sound speed field.

The basin area adjacent to the Southwest Florida shelf, the location of Site 4, is frequently influenced by the Loop Current. Figure 6 (after Brooks, 1986) shows the mean position of this relatively high salinity water mass (greater than 36.3 psu), that enters the Gulf of Mexico through the Yucatan Channel. Once in the Gulf of Mexico, this current extends northerly and easterly in a wide loop before exiting the Gulf via the Florida Strait. Temporally, this well documented feature grows in width and northerly extent and alternately shrinks as a result of shedded eddies that migrate toward the western Gulf. As evidenced by the sound speed structure and the nonstationarity of the acoustic receiving arrays, Site 4 was clearly affected by the Loop Current. Over the 18 hours during which the arrays were implanted, they drifted in a generally southeastward direction at an average rate of 94 cm/sec (1.8 kt). The sound speed variability resulting from the Loop Current influence was limited to a somewhat uniform increase in sound speed values in the upper water column with evidence of no significant gradient changes.

Both Conductivity-Temperature-Depth (CTD) and Expendable Bathythermograph (XBT) measurements were made to quantify the oceanographic variability during the exercise. CTD data was taken with an Ocean Sensors model 100 probe. This device is preprogrammable using a host computer for type of data desired (in raw counts or engineering units),

**Figure 6. General Circulation Pattern in the Eastern Gulf of Mexico and the Strait of Florida (from Brooks, 1986).**

sampling strategy (time series, vertical cast, sampling commencement triggered on depth, time, salinity, etc.), and data collection frequency. Sensor outputs are stored in internal RAM and uploaded to the host computer (in this case, a Macintosh SE 30) upon retrieval. After the exercise, the probe was recalibrated and the data was postprocessed to account for sensor drift. The specifications of this unit are shown in table 3.

Table 3. Ocean Sensors Model OS100 CTD Specifications

<i>Conductivity</i>
Measurement Range: 0.1 to 70 mS/cm
Accuracy: $\pm 0.1$ mS/cm
<i>Temperature</i>
Measurement Range: -2.0 to +30°C
Accuracy: $\pm 0.01$ °C
<i>Depth</i>
Measurement Range: 0 to 1000 m
Accuracy: $\pm 0.5$ m
<i>Salinity</i>
Computed using Unesco 1978 equation
Measurement Range: 0 to 40 psu
Accuracy: $\pm 0.03$ psu

XBT data was collected using Sippican Model T-10 probes that measure temperature to a depth of 200 m. Specifications are presented in table 4.

Table 4. T-10 Expendable Bathymeter Specifications.

Depth Resolution: 60 cm
System Accuracy: 0.2 °C
Resolution: 0.1°C
Range: -2.0 - 38°C

The data from this probe was processed using a Sippican MK-IX data acquisition system and stored on a Macintosh SE-30 personal computer. This data was postprocessed using the most temporal and spatially suitable CTD salinity values entered into Wilson's (1960) sound equation to produce sound speed vs. depth profiles. Three CTD lowerings and 11 XBT probes were collected during the exercise. Table 5 contains a tabulation of those oceanographic measurements that were used to characterize the sites and acoustic propagation paths. Tabulations and plots of the data listed in table 5 are contained in appendix A.

Table 5. Oceanographic Measurements Pertinent to the Acoustic Propagation Paths.

### IIC. GEOLOGY/GEOACOUSTIC DATA

The continental shelf bordering the west coast of Florida is part of an extensive system of carbonate banks that dominates the majority of the southeastern Gulf of Mexico and the west-central Atlantic Ocean. As illustrated in figure 7, bathymetric relief across the West Florida shelf is low, broken up by occasional reef outcrops. The continental shelf extends westward to approximately 74 m in water depth. Average slope gradient changes from approximately 0.4 to 1 m/km on the shelf to approximately 6 to 9 m/km on the continental slope. Transition from shelf to upper slope takes place through a series of steps or breaks composed of either reef material or outcrops separated by areas of gentler slope and sediment accumulation (Doyle and Holmes, 1985). Westward toward the West Florida Escarpment, the gradient gradually increases. The escarpment marks a major topographic transition, with a relief in excess of 3,050 m and slopes of more than 500 m/km (Mitchum, 1978). Surficial sediments in the study area (figure 8) range from calcareous muddy sands on the shelf and slope to calcareous turbidites and distal Mississippi fan deposits at the base of the escarpment.

Structurally, the west Florida platform is constructed of approximately 10 km of Cretaceous age to Holocene age carbonates and evaporates resting on a patchwork basement of Precambrian age to Jurassic age igneous, metamorphic, and sedimentary rocks (Holmes, 1985). At frequencies above 50 Hz, relevant acoustic energy pertinent to acoustic sensors probably does not interact with sub-bottom materials more than a few hundred meters below the sediment-water interface. Therefore, the region of principal interest for this study is the Pliocene-Holocene age (5.3 mya - present) calcareous unconsolidated to semi-consolidated deposits. The lithified upper Miocene age (~5.3 mya) and

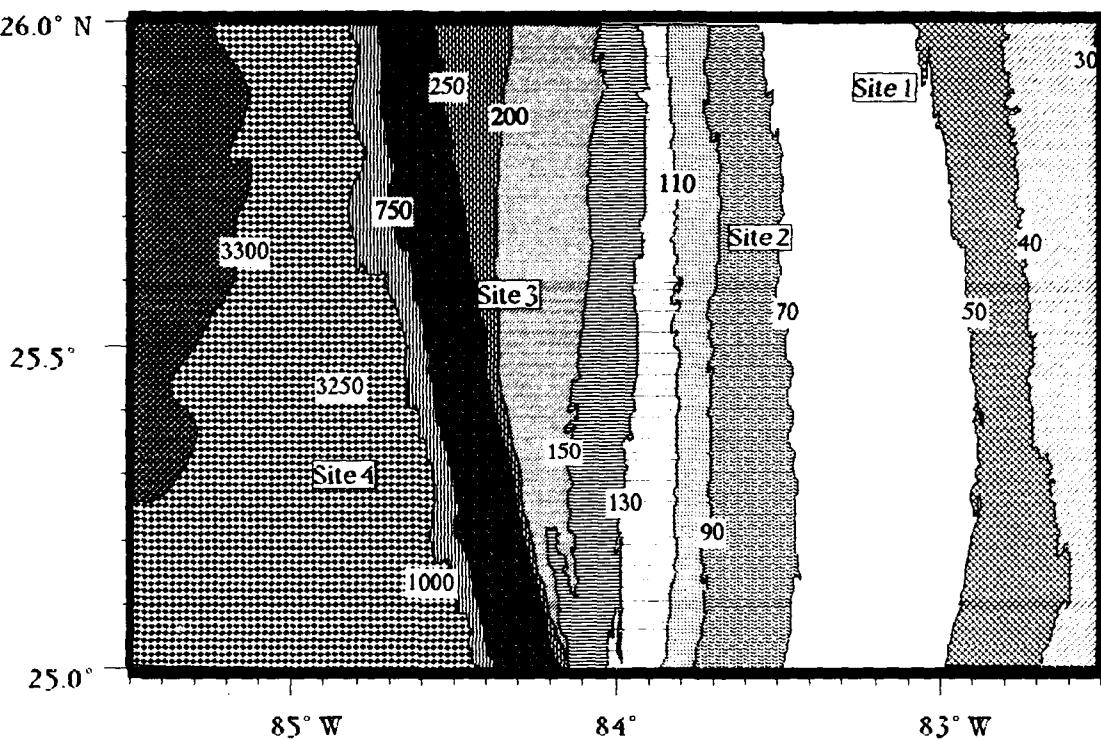

Figure 7. General bathymetry and location of test sites.

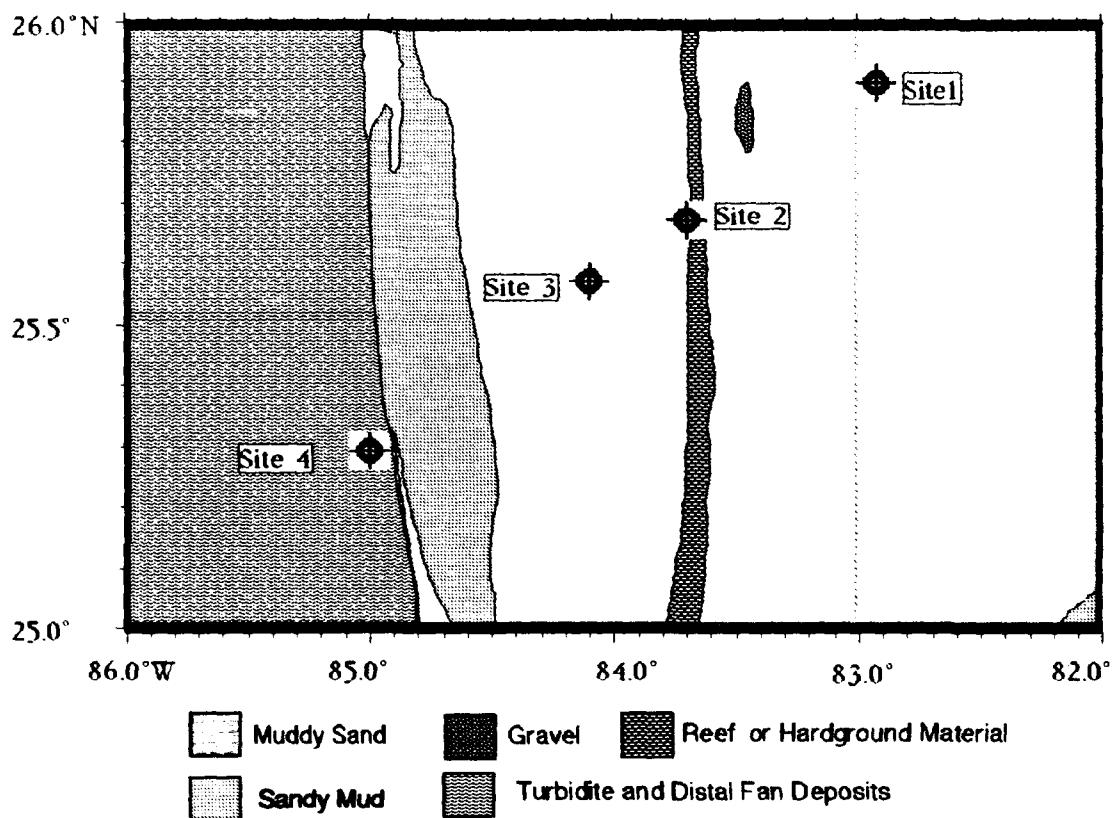

Figure 8. Surficial sediment distribution.

older sediments effectively represent acoustic basement. Structural contour maps of the Miocene horizon (Holmes, 1985) indicate that the horizon gently dips to the west, with a break in slope at mid-shelf from 0.07° on the inner shelf to about 0.2° on the outer shelf. Depth to the Miocene unit ranges from about 70 m at Site 1 to over 500 m at Site 4. The sediments overlying the Miocene can be divided into two stratigraphic units. The lower unit consists of a wedge of sediment composed of numerous discontinuous and cross-cutting reflectors of Pliocene-Pleistocene age which is a probable result of sea level fluctuations. The upper unit is a thin wedge of progradational sediments (Holocene age) that reaches a maximum thickness seaward of the shelf break. The boundary between the two units is marked by a distinct angular discordance due to erosion.

Geoacoustic models for the test area (tables 6-8) were developed in large part from seismic refraction measurements as presented in Antoine and Ewing, (1963). These models were constructed in the manner of Hamilton (1980) and are largely based upon average sediment properties and not direct measurements in the area of interest. At Site 4, physical properties of the sub-bottom (lithology, compressional velocity, and density,) were based upon results of Deep Sea Drilling Program (DSDP) Leg 96, Site 623.

## **IID. BATHYMETRY**

A AN/UQN-4 echo sounder with a 12-kHz transducer was used to collect bathymetric data. This device provides both an analog and digital readout of bathymetric sounding depths and was set to calculate two way travel time of the transducer output based on an integrated water sound speed of 1463 m/s. Depths were corrected to 1500 m/s using Matthew's tables in the Handbook of Oceanographic Tables (1966), and for vessel draft. The accuracy of the digital readout is +/- 1 digit of depth in addition to the typical system accuracy.

Figure 7 shows the relationship of the exercise sites to the regional bathymetry. Sites 1 and 2 are located on the shallow waters of the continental shelf, Site 3 is on the slope and Site 4 is at the base of the slope in the basin. An approximately 1 nmi<sup>2</sup> bathymetric site survey was taken at exercise Sites 1, 2, and 3 prior to array deployment and continuous soundings were recorded along each acoustic propagation track during the sound-source tow. Since both receiving arrays at Site 4 were free-drifting and not moored to the bottom, a bathymetric site survey was unnecessary. They were in fact moving rapidly due to the strong currents at this location. The seafloor topography at all sites and along all propagation paths were extremely invariable. Those propagation paths oriented downslope or upslope maintained a very steady slope along their entire paths. Table 9 contains a tabulation of the corrected bathymetric soundings at the beginning and the end of each radial for all four sites.

**Table 9. Seafloor Depths Along the Acoustic Paths (in corrected meters).**

## **III. NAVIGATION DATA**

Navigational positioning was accomplished using a Magnavox Model 4400 (MX4400) Global Positioning System (GPS) augmented with a rubidium time standard to provide fixes using only two satellite constellations. The MX 4400 is a two channel L1 C/A code GPS receiver. One channel sequences among the best set of up to four satellites forwarding data to the Kalman filter for processing. The second channel continually evaluates those satellites being used, updates the almanac and ephemeris for visible satellites, and takes initial

range measurements to newly visible satellites. Accuracy of GPS fixes is more dependent on the satellite constellation dilution of precision and signal-to-noise ratio at the time of each fix than on the type of receiver used. Under optimum conditions, the MX 4400 has a demonstrated accuracy of better than 25 m. GPS coverage during the timeframe of the exercise was nearly continuous.

GPS receiver output was logged at 2-minute intervals by HYPLOT, a commercial navigational aid package. Using HYPLOT, the courses of the acoustic propagation paths were entered into a subroutine that displays the track on a computer screen. As the vessel proceeded along the predesignated track, its position was displayed in real time thereby enabling the maintenance of a precise course. The navigational output was entered into a rectification program that calculated the speed and bearing between adjacent fixes. Very few fixes necessitated adjustment to reflect realistic courses or speeds. Occasionally, however, the HYPLOT output was incomplete and the navigation during these periods was rectified using the backup hand logged data. Rectified navigation was then entered into a program that calculated range and bearing at 2-minute intervals between the acoustic arrays and the moving source. Plots and tabulations of these source-to-receiver ranges along each acoustic propagation path are presented in appendix B.

#### **IIIF. METEOROLOGY**

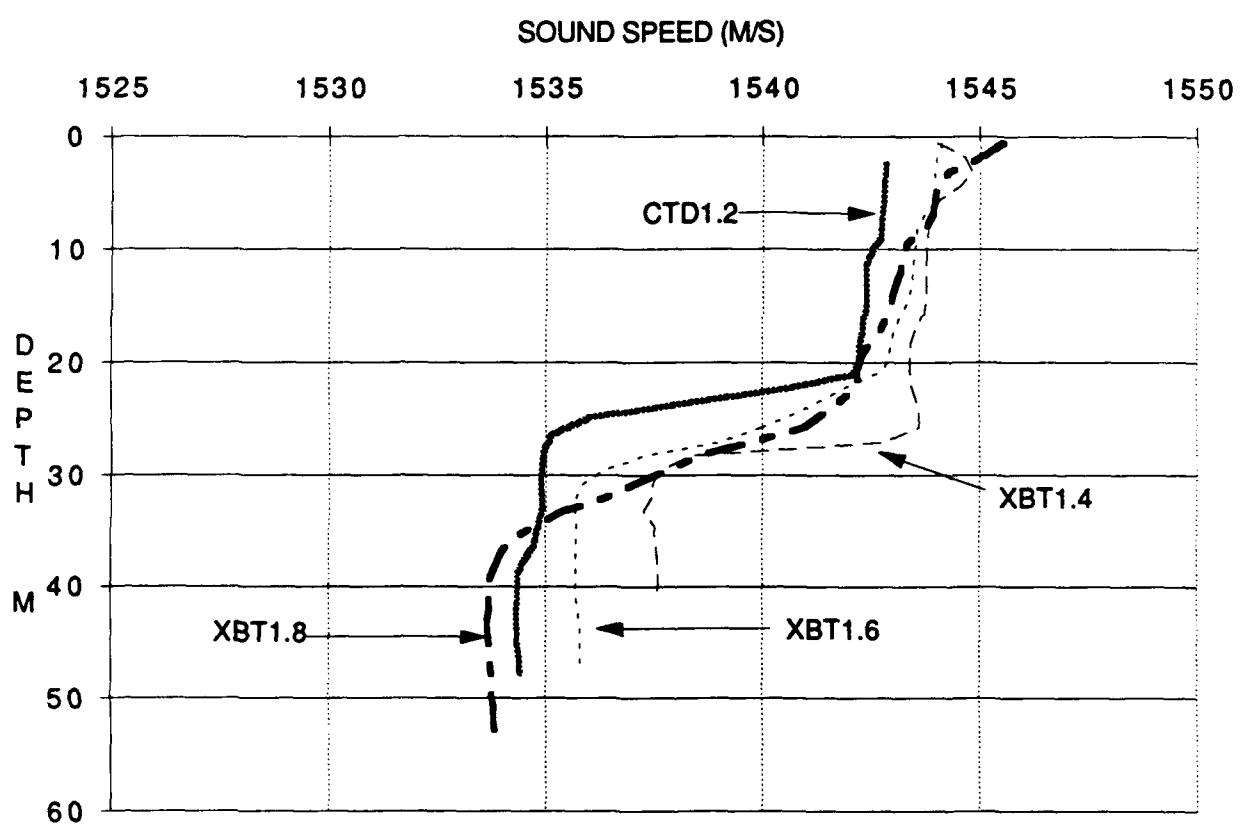

Meteorological conditions were very homogeneous throughout the acoustic measurement period. The sea surface was glassy-to-lightly rippled, reflecting a Beaufort code one. Winds ranged from calm to 5 km/hr throughout the period.

*Form Approved  
OMB No. 0704-0188*

Public reporting burden for this collection of information is estimated to average 1 hour per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Send comments regarding this burden or any other aspect of this collection of information, including suggestions for reducing this burden, to Washington Headquarters Services, Directorate for Information Operations and Reports, 1215 Jefferson Davis Highway, Suite 1204, Arlington, VA 22202-4302, and to the Office of Management and Budget, Paperwork Reduction Project (0704-0188), Washington, DC 20503.

13. Abstract (Maximum 200 words).  <p>During 14 through 20 June 1991, an active acoustics exercise was conducted under the auspices of the Program Executive Officer of the Air, ASW, Assault and Special Mission Programs office. This exercise was located on the continental shelf, slope and in the basin between the Florida Keys and St. Petersburg, Florida. The objective of this mission is to make noise, reverberation and transmission loss measurements using fully calibrated sources, receivers, and recording devices. This data set is intended to support the validation of candidate shallow-water transmission loss and reverberation models for use in the development of next generation airborne ASW sensor systems. To adequately interpret the exercise results and to support the modeling effort, a robust suite of supporting environmental measurements were made aboard the research vessel NADC-38, owned by the Naval Air Development Center (NADC). These measurements include a depiction of the sound speed structure, bathymetry, meteorological conditions, and navigation along 11 projector tow tracks and at 3 drifting ambient noise and 4 reverberation sites. This technical note provides a brief description of the oceanographic and geological structure in the exercise area followed by a compendium of the collected data.</p>
